

BROWN & WILLIAMSON TOBACCO CORPORATION

INTERNAL CORRESPONDENCE

TO: MR. P. H. HARPER ✓
CC: DR. P. L. AULBACH
FROM: MR. D. S. ROTH/911
INTERNATIONAL & EXTERNAL TECHNICAL SERVICES DEPARTMENT
DATE: APRIL 22, 1982
SUBJECT: INFORMATION FOR LUXEMBOURG

Per your request of 3-17-82 to Dr. Aulbach, the information for Luxembourg is as follows.

1. The typical N-heptane flotation percentage for puffed tobacco is 90-95%. This value is obtained by dividing the dry weight of the recovered, floated material by the dry weight of the sample. Values below 90% are most unusual.
2. Residual freon levels are dependent on: the design and operation of the G-13 process equipment, and the handling and time lapse after expansion. Freon is lost continuously until the residual level is very low.

At these extremely low levels, we have never seen any impact on smoke taste from Freon.
